Abstract

Contract No. Da28 043 AMC 02135 (E)

The principal physical condition causing constructional difficulties in both the 1-3/4 X 3-1/4 inch and 1-1/8 X 1-1/8 inch cell size batteries was the evolution of gas during storage and discharge. A revision in seel construction and moisture barrier size reduced the failure rate, particularly on the 1-1/8 X 1-1/8 inch cell size.

A protective coating to prevent corrosion of the non-reactive side of the anode 12 necessary to prevent corrosion of the electrical contact area of the anode.

A magnesium wafer battery cannot be contained within a specified dimension due to expansion of discharge products. Provision must be allowed for this expansion in battery design. Special measures to contain the expansion reduces the capacity of the battery.

It should be possible to build a 1-1/8 X 1-1/8 inch cell size battery with a 90% survival rate when stored one month at 160°F.

The Impedance-Phase Angle measurements, particularly phase angle, on complete wafer barraries is a potentially useful method of determining the condition of a battery in a non-destructive manner.

Publications, Lectures, Reports and Conferences

Publications: None

Reports: None

Lectures: None

Conferences:

1. 14 March 1968, outlined progress to date and discussed contract completion requirements. Held at ECOM, Fort Monmouth, New Jersey. Attended by Donald B. Wood of the U. S. Army Electronics Command and Howard J. Strauss and Lloyd W. Eaton of Burgess.

Cell and Battery Construction

The objectives proposed in the Semi-Annual Report ECOM 02135-5 were as follows:

- 1. Verify the theory that the contact area protection from moisture requires complete protection of the non-active side of magnesium anode.
- 2. Datermine the most effective material for providing the corrosion protection of the non-reactive side of the magnesium anode.
- 3. Verify the supposed destructive effect of perchlorate on rubber hydrochloride cell wrap.
- 4. Qualify PZ2000.21 (Dow) film as a cell wrap material for perchlorate mix cells.
- 5. Qualify polyethylene coated paper as a cell wrop maderial for perchlorate mix cells.
- 6. Test seamed cans for the 1-1/8" X 1-1/8" size batteries, as full F_1 sections of the Bu4270/U, for containment of the cell expansion.
- 7. Devise a wax proof gas leak device, i.e. one that does not plug with wax during potting, for 1-1/8" X 1-1/8" size battery to relieve the hydrogen has, produced on discharge, that is contained by the sealing in a fresh battery.
- 8. Test methods of redistributing expansion forces in the Ba-4386/PRC-25 flat cell battery employing a cell measuring 1-3/4" X 3-1/4" to allow containment of the battery within the design limits.
- 9. Assuming perchlorate battery call wrap problems are overcome and a surviving battery call made, determine the delay characteristics of voltage build-up.

10. Mest batteries stored at 145°F.

Moisture Protection of Contact Area

It was found that if any bare metal exists on the non-active side relative to the cell of the magnesium anode corrosion will start at this bare section and proceed under all protective materials surrounding the contact area, producing variable corrosion of the contact area and this in turn results in slight resistance increase to an effectively open circuit.

The following .asterials and methods were tried to protect the contact area;

- 1. H. B. Fuller Co. HM 113R hot melt adhesive smeared over entire non-active side of anode except 1/4 inch diameter contact area.
- 2. National Starch 34-3104 hot melt adhesive applied in the same manner.
- Coast-to-Coast Spray Paint of the following code numbers without a primer coat.
 - a. GPO-224-8
 - b. GP-207
 - c. GP-214
 - a. 78-206
 - e. GP-205
- 4. Primer spray paint used with GP-205 and GPO-224-8 spray paints
 - a. Coast-to-Coast GP-234
 - b. Cosst-to-Coost GP-230
 - c. Teapo Producte Co. No. E-2000 spray primer

The materials were tested by making complete battery units, storing for one month at 160°F., discharging, and examination. The relative results of these ande protective coatings would be:

- 1. H. B. Fuller Co. HM113R hot melt -- poor
- 2. National Starch 34-3104 hot melt -- good, if applied carefully
- 3. Coast-to-Coast spray paint

a. GFO-224-8

gout

b. GP-207

fair, minus

c. GP-214

poor

d. GP-206

feir, plus

e. Gp-205

good

- 4. Primer spray point with GP-205 and GPO-224-8 spray points
 - a. Coast-to-Chast GP-234

very poor

b. Comment of P-230

good

c. Tempo Products Co. No. 3-2000

feir, minus

The effectiveness of the paint coating is affected by the pickling process employed on the magnesium and further work is needed to obtain a uniformly effective conting that is easy to apply. The nature of the pigment in the paint also affects the ability of the coating to survive as a protective coating.

The percentage of pigment in the paint and the percentile composition of the pigment of the various paints employed are as follows:

GP0-224-8

Pigment per centage in paint	3.77%
Titanium Dioxide	40.1 \$
Chrome Yellow	48.9 %
Yellow Iron Oxide	9.9 🕏
Brown Iron Oxide	0.7 🕺
Red Iron Oxide	0.4 \$
GP-207	
Pigment per centage in paint	1.72%
Titanium Dioxide	32.5 🕏
Iron Blue	67.5 🛠
GP-214	
Pigment per centage in paint	1.40%
Toluidine Red	100. 🕏
Taluidine Red GP-206	100. \$
	100. \$
GP-20ó	,
GP-206 Pigment per centage in paint	3.025
GP-206 Pigment per centage in paint C. P. Chrome Yellow	3.02 \$ 24.5 ≸
GP-206 Pigment per centage in paint C. P. Chrome Yellow C. P. Chrome Yellow Med.	3.02 \$ >4.5 ≸ 9.1 \$
Pigment per centage in paint C. P. Chrome Yellow C. P. Chrome Yellow Med. Titanium Dioxide	3.02 \$ >4.5 ≸ 9.1 \$
GP-206 Pigment per centage in paint C. P. Chrome Yellow C. P. Chrome Yellow Med. Titanium Dioxide	3.025 94.5 \$ 9.1 \$ 36.4 \$

The Toluidine Red (GP-214) was sitered chemically in the cell during 160°F. storage and corrosion was generalized.

The Iron Blue (GF-207) would be altered chemically but the effect would be variable from total failure to isolated spots on a few cells.

The parment in GP-206 was not altered chemically but the coating tended to be porous and would "lift" from the anode and allow corrosion in variable degrees.

Effect of Perchlorate on Rubber Hydrochloride Film

MA-4386 units were made using 5N perchlorate wetter in the cathode mix and rubber hydrochloride cell wrap. Units were stored one month at 160°F, and one and three months at 130°F. Careful dismantling of the units was performed and the individual cells examined under a microscope at 16%. Small holes were found just inside the heat scaled area of the 130°F, samples. The holes are found to have joined to form a slit-like opening in the 160°F, samples that could almost be seen with the unaided eye. There openings allowed electrolyte to escape, causing massive destruction within the battery. Apparently the heat of scaling partially degraded the adjacent rubber hydrochloride film so that the perchlorate could attack the area. The unheated parts of the cell wrap apparently were not affected by the perchlorate to a detectable degree.

Qualification of PZ2000.21 (Dow) Film

This material has been found to be inert to the effect of perchlorate but suffers mechanical difficulties in obtaining an effective heat seal.

Heat sealing produced false seals and hidden extrusion-like holes that were very difficult to find even under 16% observation. Because of this characteristic the material, by itself, is unsatisfactory, but modification as a laminate with other film materials holds promise. A number of bettery units were made and are discussed in other sections of this report.

Qualification of Polyathylene Coated Paper

This material is not practical in the cell assembly employed. The heat of sealing damages the continuity of the polyethylene film in the areas adjacent to the seal. The other non-heat affected areas survive one month at 160°F. in excellent condition. The leakage allowed by this heat seal damage causes massive destruction within the battery.

Seamed Cans for 1-1/8 X 1-1/8 Inch Cell Size Batteries

The rolled seam, shown as Fig. 4 in appendix and used on both 1-1/8 X 1-1/8 and 1-3/8 X 3-1/4 inch cell size cans, would hold approximately 50% of the time on 1-1/8 X 1-1/8 cell size batteries. It cannot be relied upon to contain the batteries within the can due to the expansive pressure of the discharge products. The seamed cans were also edge welded to insure containment on most units.

Ges Leak Device

It was found that the gas produced on discharge is not escaping the individual cells as thought and being trapped in the wax costed battery

can but is actually being held within the individual calls with the can restraining the balloomed cell wrap. To be affective, each cell would require a gas leak device. It was found that as long as the discharge rate did not exceed 0.028 amp/sq. inch, on a continuous basis, the electrical contact between cells could be maintained by adjusting the degree of compression.

Containment of Ba-4386 Battery

It was found to be impossible to contain a unit within the specified design limits. The most successful method found in restricting the expansion was to weld 1/4 X 1/8 inch steel bars across the ends of the battery can, two bars per end equally spaced. Seven units were made in this manner. Three suffered some heat damage due to the welding and shorted. The resultant gas pressure caused the can seam to yield and the cell wrap exploded. Three, on discharge, ruptured the welds or tore the metal of the can. Only one was totally restricted. The capacities of the restricted units is noticeably less than the equivalent unit in which the only sustriction is the can cover itself. It would appear that to operate properly magnesium flat cell batteries must be allowed a degree of restrained expansion. Too much expansion room, i.e. addition of fibrous material or balsa wood, or too little per above experiment reduces the capacity. A possible explanation is the physical nature of the discharge product on the anode. If too much room is allowed this product is bulky and voluminous and causes too much separation in the cell increasing cell

resistance. In excessively restrained units this product becomes hard and compressed, preventing easy access of electrolyte to the anode metal, again increasing resistance. An example of this effect is shown in the A₂ sections of fresh Ba-4386 batteries using perchlorate mix.

Capacity in hours to 10.0 volts/9.0 volts

	Unit 1	Unit 2
Standard can construction	71.5/74.1	72.5/78.3
Restrictive bars	56.9/65.5	56.8/64.5
Fibrous pad	57.9/60.0	33.3/33.4

The use of 1/4 inch thick sponge rubber provided such each expansion that the gas evolution or discharge separated the current collector from the cathode, causing an open circuit to appear shortly after placing the battery on discharge.

Cell Integrity

The dominant mode of failure in both the 1-3/4 X 3-1/4 inch and 1-1/8 X 1-1/8 inch cell sizes was a degree of shorting of physical destruction due to the presence of free electrolyte outside the cells. With the exception of the PZ-2000.21 a film poor seal performance was inadequate to account for the persistent appearance of this electrolyte so microscopic examination of the 160°F, stored units was undertaken to try to trace the source of this leakage. The effect of this leakage on the 1-3/4 X 3-1/4 inch cell size batteries was much more severe than the effect on the 1-1/8 X 1-1/3 inch cell size batteries and perchlorate units

suffered more than bromide units.

An indication of the difference in severity of damage between the bromide and perchlorate units, with the construction described in ECOM 02135-5 and shown in Figs. 1, 2, and 3 of this report, i.e. hot melt ring seals and anode size moisture barriers, is shown in Table I (bromide 1-1/8 X 1-1/8 cell size) and Table V (perchlorate 1-1/8 X 1-1/8 cell size.)

The first change to improve this performance was to reduce the size of the moisture barrier to 19/32 inch diameter. The effectiveness of this change is shown in Table II (bromide) and Table VI (perchlorate) as compared to Tables I and V.

Microscopic examination of the units in Tables I, II, V, and VI (1-1/8 x 1-1/8 cell size) and Tables IX, X, XIII, and XIV (1-3/4 x 3-1/4 cell size) eventually produced a consensus as to the primary source of this leakage. It appears that the plasticizer present in the cathode current collector material migrates, at 160°F., into the hot melt ring seal between the collector and cell wrap. This alteration of the seal and the pressure of the gas produced on storage would force the seal allowing some electrotyte to escape during storage damaging the batteries. Further electrolyte is forced out of the now porcus seal by the gas pressure generated during discharge adding to the damage.

The second change in cell construction was the replacement of the hot melt ring seal between the cathode current collector and cell wrap with 3-M Company's No. 666 adhesive tape the same size as the cathode current collector. Holes were provided for contact to the current collector.

The effect of this change on the 1-1/8 X 1-1/8 cell size units is shown

as Series 1 and 2 of Table III (bromide.)

This change totally stopped the leakage occurring at the cathode current collector seal but caused an increase in failure rate on discharge due to disconnection of the current collector in one or more cells by the pressure of the gas generated on discharge. The ring seals had, apparently, provided a form of gas leak. The compression was increased by either cutting the battery can down in size or increasing the cathode mix content approximately 4.5%. This effect is shown in Table III, series 3-6, Tables VII, VIII (1-1/8 X 1-1/8 cell size) and Tables XI and XV (1-3/4 X 3-1/4 cell size.)

Corrosion of the anode contact reappeared in the units employing the tape seal between the cathode current collector and cell wrap. Careful examination of cells from these units indicated that the hot melt ring seal between the anode and cell wrap was now being forced by the increased gas pressure, during storage at 160° F., due to seal improvement on the collector. This effect was largely confined to the 1-3/4 X 3-1/4 cell size. The 1-1/8 X 1-1/8 cell size apparently did not produce enough gas on storage to cause this damage to any degree.

The third change in cell construction was to replace the ring seal on the painted anode with a 1 X 1 inch piece of No. 666 tape. This tape esal between the cell wrap and anode and current collector totally stopped leakage at these points. Any leakage found in these units resulted from true heat seal failure of the cell wrap. Units made in this manner are listed in Tables IV and VIII (1-1/8 X 1-1/8 cell size) and Tables XII and

XVI (1-3/4 X 3-1/4 cell size.)

Phase Angle and Impedance

Very late in the contract period a Hewlett-Packard Vector Impedance Meter Model 4800A was obtained to study the phase angle and impedance characteristics of the Pa-4386 units, the purpose being to determine the condition of the battery before and after storage by non-destructive means. Although the data is limited, the results are favorable and indicate that the impedance-phase angle measurements, and particularly the phase angle, can be correlated, to a degree, with various conditions within a battery.

As noted in earlier sections of this report, leakage of electrolyte was the singular most serious source of failure and a non-destructive means of detecting this leakage and locating the source was one of the prime objectives of this work.

The data, indeed, did point to a common characteristic for batteries with leakage that separated them from normal units. This characteristic is a marked downward deviation of the phase angle from tolerance limits established for normal units without leakage. The tolerance limits were determined by the pragmatic method of measuring a number of units. All fresh units showing this deviation destroyed themselves during storage at 160°F. The impedance measurements seemed to have intuitive value but were difficult to tie in specifically to any particular condition. There appeared to be some correlation of the impedance to electrical contact between cells and dryness of the cathode.

The phase angle of units, after storage one month at 160°F., showed deviation from the fresh state when leakage occurred during storage. Units that show little or no deviation from the fresh norm could be expected to perform properly. Units with deviation ran poorly compared to non-deviant units.

The impedance increased generally after storage more so at the lower frequencies. Bromide electrolyte battery impedance were generally higher than perchlorate electrolyte batteries. Severe impedance increase after storage with little phase angle deviation usually indicated corrosion of the electrical contacts on the anode.

The Hewlett-Packard Model 4800A Vector Impedance Meter is provided with a direct measurement plug-in that allows an external circuit that is to be measured to be applied directly to the instrument and phase angle, impedance, resistance and capacitance or inductance can be read directly on meters incorporated in the instrument. The frequency is adjustable over 5 HZ to 500 KHZ in five bands. Frequencies beyond 10 KHZ were of no value in this work. The nature of the instrument is such that the DC voltage of the battery must be blocked so a 20,000 MFD capacitor was interposed between the test batteries and instrument. The impedance of this capacitor is of no consequence in the readings. There is a phase angle shift resulting from this capacitor, but it is essentially constant over the range and does not seem to affect the interpretations of the battery results. The instrument is such that the frequency can be swept by an external oscillator over a given decade and the impedance and mase angle, through an analog output that is provided, read out

on an oscilloscope and the trace photographed. Due to the application being a little unusual for the equipment, some difficulty was experienced in its operation and adjustment and a modification of the meter was required. This limited its use during the contract period to manual adjustment of the frequency and the period of time available for measurements was too short for extensive data.

The meter supplies a test signal to the unknown circuit less than 2.2 millivolts RAS in the range employed. The current of the injected signal is held constant by the meter's circuitry and the impedance is directly proportional to the voltage. The phase angle is determined within the meter by circuitry that compares the signals from the voltage and current channels.

The fresh bromide mix units of Series 5, Table XI and Series 2, Table XII were measured for impedance and phase angle at various frequencies. The phase angle characteristic of the series is represented by the following average values with the tolerance deviation spread including every unit measured except Unit #1 of Series 5, Table XI.

A Bection

	<u> </u>		
Frequency - Hz	Average Phase Angle	Tolerand Plus	Minus
30 40 60 80 100 200 400 600 800 1K 2K 5K	77° 75 72 69 67 60 50 42 37 33 24	2° 3 5 7 6 8 10 10 10 9 8 6	o 235446898664
Frequency - Hz	A Section Average Phase Angle	Plus	Minus
30 40 60 80 100 200 400 600 800 1K 2K 5K	75° 7 ¹ 69 67 63 51 38 31 24 21 11 Inductive	5° 4 6 6 7 9 11 7 9	3 5 4 6 6 8 9 9 7 6 5

The A_2 section tolerance deviation spread of the fresh tromide units is shown in Figure 5 as two solid lines. The cross points represent the fresh phase angle value of the first battery of Series 5, Table XI. This unit was the only unit of the two series with a serious deviation outside the tolerance limit. The unit destroyed itself within one week when stored at $160\,^{\circ}$ F. The deviation was caused by leakage of electrolyte. This unit did not show any variation from the norm in either voltage or current producing ability. The A_1 section values of the same units are plotted in Figure 6 with the cross point values of the above noted unit #1 of Series 5, Table XI. The leakage source would appear to be in the A_2 section.

The units of Series 5, Table XI were measured for impedance and phase angle after storage for one month at 160°F. Units 2, 4, 5, and 6 showed open circuit in the A₂ section. These units were opened and some leakage was found that had corroded the A₂ positive lead. This lead was replaced and the units recanned and discharged. Units 3, 7, 8, 9, and 10 A₂ section phase angle data is shown as cross points at Fig. 7. The two solid lines are the fresh deviation tolerance limits noted earlier. It will be noted that very little change occurred in the phase angle. Fig. 8 shows the same data for the A₁ section of these units. Also little deviation will be noted. The impedance data noted for the A₂ section in Fig. 9 shows a significant change had occurred. The two lines for fresh and after 160°F, storage encompass every unit of the series and are essentially maxims and minima points for the various frequencies. Examination of these units showed that the gas pressure, produced during storage and trapped by the cathode collector tape seal, had forced the hot melt smear seal, allowing

electrolyte to escape at the electrical contact point on the snods. Considerable corrosion of this contact was found and the free electrolyte had caused the \mathbb{A}_2 positive lead to be destroyed or so close to being destroyed that further action on discharge completed the destruction of the lead.

The phase angle and impedance data for A₂ sections of units of series 1 Table 12 that were stored one month at 145°F, is shown in the same manner in Figs. 10 and 11. Due to equipment not being available at the time fresh data was not obtained on these units. The fresh phase angle data is assumed to be covered by the deviation limits described earlier in this report. The fresh impedance data is assumed to be equivalent to that of Series 2, Table XII. Acceptance of this fresh data limit indicates little deviation of phase angle and impedance occurred during storage and the units could be expected to discharge with reasonable capacity, which was the case.

The fresh perchlorate units of Series 8, Table 15 and Series 1 of Table 16 were also measured for impedance and phase angle with the following average values and tolerance limits.

The tolerance deviation spread of A_2 and A_1 sections are shown as solid lines in Figs. 13 and 14. The cross point values are of a unit from Series 1, Table XV. This series failed due to leakage of electrolyte resulting from faulty PZ2000.21 heat seals. The voltages were normal and nothing appeared amiss at the time. The deviation in phase angle is severe in both the A_2 and A_1 sections. The impedance values of the fresh units did not show this deviation.

The perchlorate units of Series 1, Table 16 and Series 8, Table 15 were measured for impedance and phase angle after storage for one month at 160°F. The results of the phase angle measurements of the A sections are shown as cross points in plots on Figures 15 and 16 respectively. The deviation from the fresh values is not great, indicating little or no leakage. This was substantiated on examination after discharge. The impedance limits of the A2 sections of these units both fresh and after storage is shown in Figures 17 and 18. It will be seen from these plots an increase in impedance had occurred during storage. The units of Series 8, Table 15 (Fig. 18) experienced failure of the hot melt smear seal between the anode and cell wrap and a degree of corrosion was present on the contacts. Nothing could be found to account for the impadance shift of Series 1, Table 16 units. The most probable cause is a lack of electrolyte in the mix to carry the unit. The per centage of electrolyte had been reduced earlier in the project to ease physical problems in construction. The capacities of the units were fairly consistent and could be accounted for by electrolyte shortage.

CONCLUBIONS

- The principal condition causing constructional difficulties was the evolution of gas during storage and on discharge.
- 2. Magnesium wafer batteries should not be restricted by extraordinary means to keep discharged unit within specifications. Room should be allowed for this expansion in the design.
- 3. The non-reactive side of the magnesium needs protection against corrosion in order to maintain a clean, conductive location for electrical contact.
- 4. A bettery with 1-1/8 X 1-1/8 inch cell size can be made with reasonably consistent capabilities.
- 5. The phase angle and impedance of a battery at various frequencies probably is a useful way of characterizing the condition of a battery in a non-destructive manner.

A-1

The code employed in Tables 1 - 16 to denote various constructional features is as follows:

Code Letter	Significance		
A .	Cell Wrap rubber hydrochloride		
В	Cell Wrap polyethylene laminated paper		
C	Cell Wrap Dow FZ2000.21 film		
R	Anode Coating Fuller's HM-113 R smeer		
8	Anode Coating National Starch 34-3104 smear		
T	Anode Coating Spray paint without primer		
U	Anode coating Spray paint with primer

13 ABSTRACT

The principal physical condition causing constructional difficulties in both the $1-3/4 \times 3-1/4$ inch and $1-1/8 \times 1-1/8$ inch cell size batteries was the evolution of gas during storage and discharge. A revision in seal construction and moisture barrier size reduced the failure rate, particularly on the $1-1/8 \times 1-1/8$ cell size.

A protective coating to prevent corrosion of the non-reactive side of the anode is necessary to prevent corrosion of the electrical contact area of the anode.

A magnesium wafer battery cannot be contained within a specified dimension due to expansion of discharge products. Provision must be allowed for this expansion in battery design. Special measures to contain the expansion reduces the capacity of the pattery.

It should be possible to build a 1-1/8 X 1-1/8 inch cell size battery with a 90% survival rate when stored one month at 160°F.

The Impedance-Phase Angle measurements, particularly phase angle, on complete wafer batteries is a potentially useful method of determining the condition of a battery in a non-destructive manner.

INSTRUCTIONS

- 1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, granter, Department of Defense activity or other organization (corporate author) fashing the report.
- 2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Dato" is included. Marking is to be in accordance with appropriate security regulations.
- 25. GROUP: Automatic downgrading is specified in DoD Directive 5200. 10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.
- 3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification is all capitals in parenthesis immediately following the title.
- 4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.
- 5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial, if military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.
- REPORT DATE: Enter the date of the report as day, month, year; or menth, year. If more than one date appears on the report, use date of publication.
- 7a. TOTAL NUMBER OF PAGES: The total page count should follow normal nagination procedures, i.e., enter the number of pages containing information.
- 75. NUMBER OF REFERENCES. Enter the total number of references cited in the report.
- 8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriamilitary department identification, such as project number, subproject number, system numbers, task number, Mc.
- 9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official upport number by which the document will be identified and introlled by the criginating activity. This number must be unique to this report.
- 98. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).

10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain captar of this report directly from DDC. Other gualified DDC users shall request through
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

- 11. JUPPLEMENTARY NOTES: Use for additional explana-
- 12: SPONSORING MILITARY ACTIVITY: Exter the name of the departmental project office or laboratory aponsoring (paying (or) the conserva and development. Include address.
- 13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elementers in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a roport and may be used as index entries for cataloging the report. Key words must be selected so that no necurity classification is required. Idenfiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, rules, and weights is optional.
